STEP-LESS 3-DIMM CLOCK

1. GENERAL DESCRIPTION

The W83194BR-39B is a Clock Synthesizer, which provides all clocks required for high-speed RISC or CISC microprocessor such as Intel Pentium II or Pentium III. W83194BR-39B provides 64 CPU/PCI frequencies, which are selectable with smooth transitions by hardware or software. W83194BR-39B also provides 13 SDRAM clocks controlled by the none-delay buffer in pin.

The W83194BR-39B provides step-less frequency programming by controlling the VCO freq. and the programmable PCI clock output divisor ratio. A watchdog timer is quipped and when time out, the RESET# pin will output 4ms pulse signal.

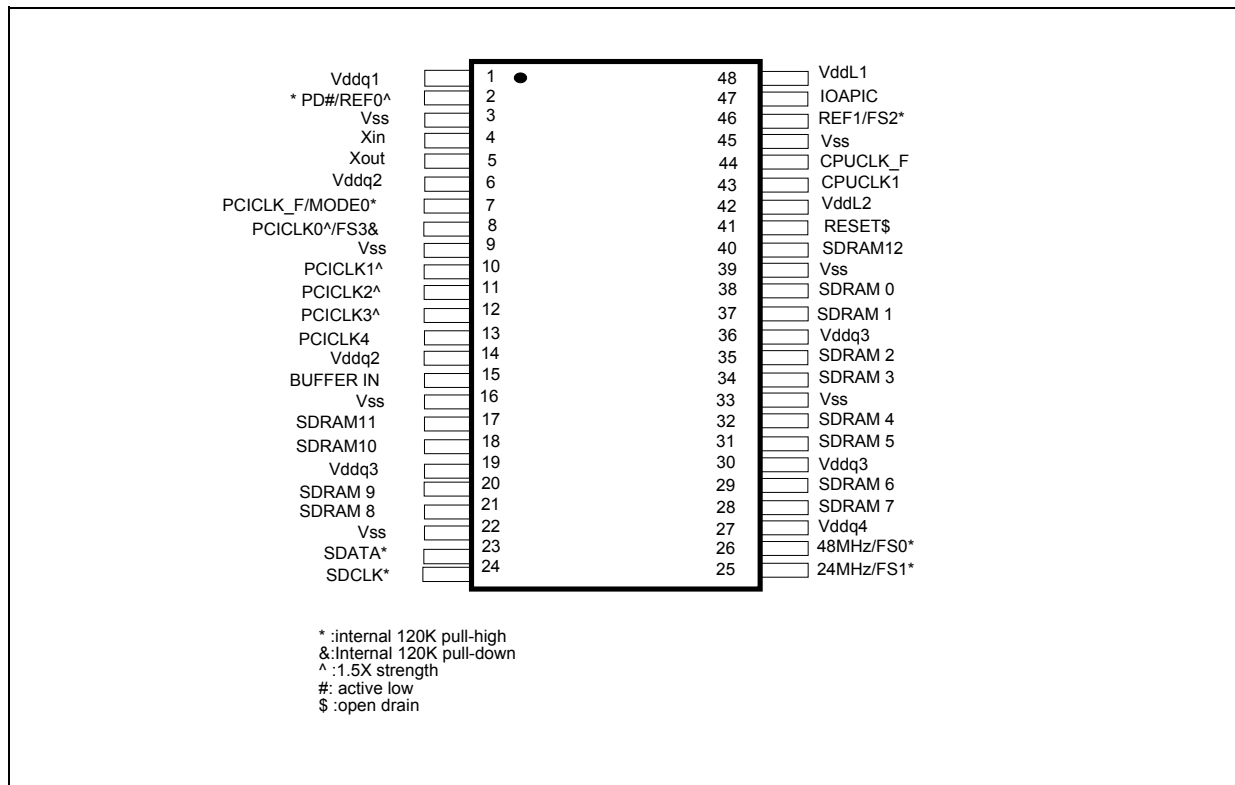

The W83194BR-39B accepts a 14.318 MHz reference crystal as its input. Spread spectrum built in at $\pm 0.5\%$ or $\pm 0.25\%$ to reduce EMI. Programmable stopping individual clock outputs and frequency selection through I²C interface. The device meets the Pentium power-up stabilization, which requires CPU and PCI clocks be stable within 2 ms after power-up. Using dual function pin for the slots (ISA, PCI, CPU, DIMM) is not recommend.

8. FUNCTION DESCRIPTION

8.1 2-WIRE I²C CONTROL INTERFACE

The clock generator is a slave I²C component, which can be read back the data, stored in the latches for verification. All proceeding bytes must be sent to change one of the control bytes. The 2-wire control interface allows each clock output individually enabled or disabled. On power up, the W83194BR-39B initializes with default register settings. Use of the 2-wire control interface is then optional.

The SDATA signal only changes when the SDCLK signal is low, and is stable when SDCLK is high during normal data transfer. There are only two exceptions. One is a high-to-low transition on SDATA while SDCLK is high used to indicate the beginning of a data transfer cycle. The other is a low-to-high transition on SDATA while SDCLK is high used to indicate the end of a data transfer cycle. Data is always sent as complete 8-bit bytes followed by an acknowledge generated.

Byte writing starts with a "start" condition followed by 7-bit slave address and a write command bit [1101 0010], command code checking [0000 0000], and byte count checking. After successful reception of each byte, an "acknowledge" (low) on the SDATA wire will be generated by the clock chip. Controller can start to write to internal I²C registers after the string of data. The sequence order is as follows:

Bytes sequence order for I²C controller:

Clock Address A(6:0) & R/W	Ack	8 bits dummy Command code	Ack	8 bits dummy Byte count	Ack	Byte0,1,2... until Stop
----------------------------	-----	---------------------------	-----	-------------------------	-----	-------------------------

Set R/W to 1 when read back", the data sequence is as follows:

Clock Address A(6:0) & R/W	Ack	Byte 0	Ack	Byte 1	Ack	Byte2, 3, 4... until Stop
----------------------------	-----	--------	-----	--------	-----	---------------------------

STEP-LESS 3-DIMM CLOCK

8.2 SERIAL CONTROL REGISTERS

The Pin column lists the affected pin number and the @PowerUp column gives the default state at true power up. "Command Code" byte and "Byte Count" byte must be sent following the acknowledge of the Address Byte. Although the data (bits) in these two bytes are considered "don't care", they must be sent and will be acknowledge. After that, the sequence described below (Register 0, Register 1, Register 2...) will be valid and acknowledged.

10. OPERATION OF DUAL FUNCTION PINS

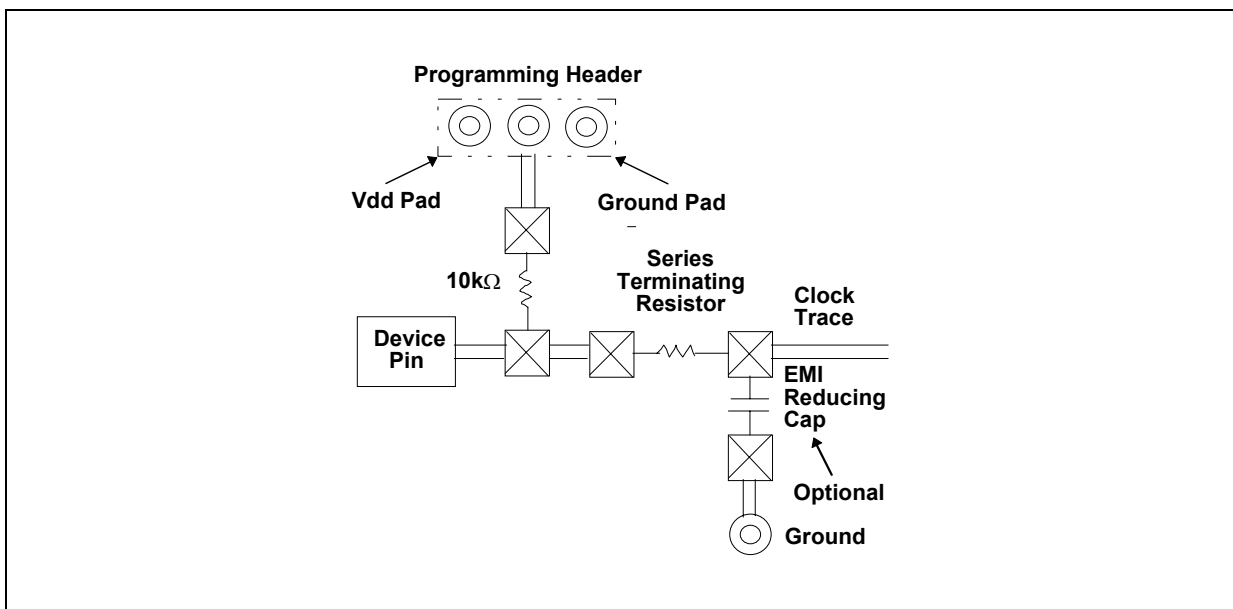

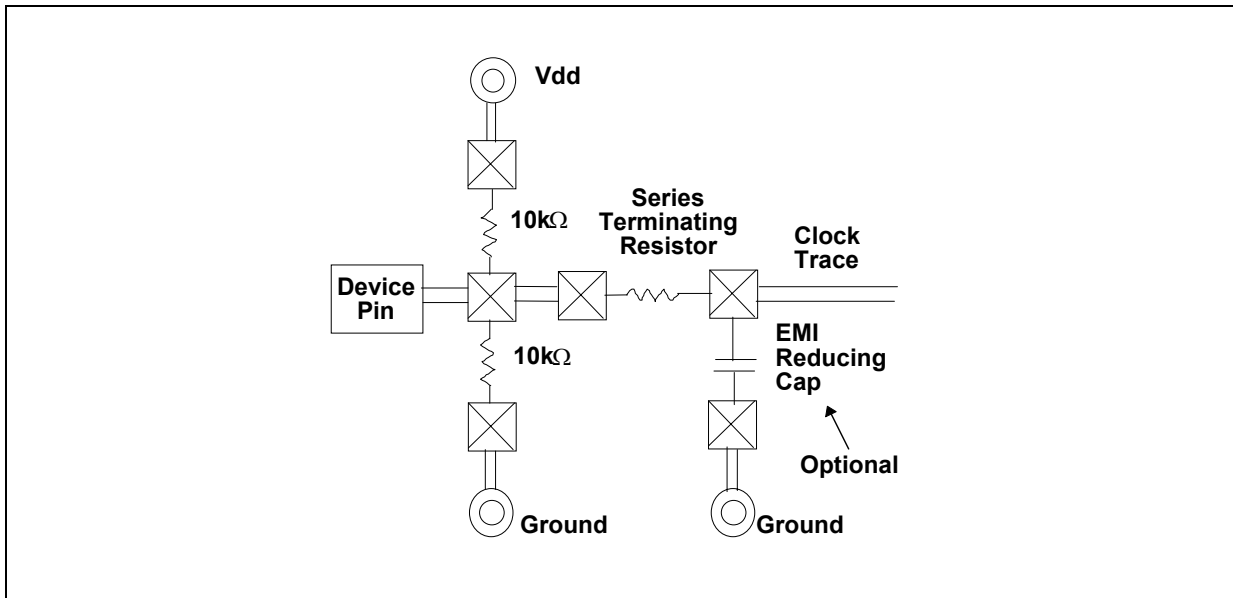

Pins 2, 7, 8, 25, and 26 are dual function pins and are used for selecting different functions in this device (see Pin description). During power up, these pins are in input mode (see Fig1), therefore, and are considered input select pins. When Vdd reaches 2.5V, the logic level that is present on these pins is latched into their appropriate internal registers. Once the correct information is properly latched, these pins will change into output pins and will be pulled low by default. At the end of the power up timer (within 3 ms) outputs starts to toggle at the specified frequency.

Each of these pins has a large pull-up resistor (250 k Ω @3.3V) inside. The default state will be logic 1, but the internal pull-up resistor may be too large when long traces or heavy load appear on these dual function pins. Under these conditions, an external 10 k Ω resistor is recommended to be connected to Vdd if logic 1 is expected. Otherwise, there should be direct connection to ground if a logic 0 is desired. The 10 k Ω resistor should be placed before the series terminating resistor. Note that this logic will only be latched at initial power on.

If optional EMI reducing capacitors are needed, they should be placed as close to the series terminating resistor as possible and after the series-terminating resistor. These capacitors have typical values ranging from 4.7pF to 22pF.
